Axial Lisp Naming Canon

Formal identity

```
Axial Lisp
```

is the homoiconic, multi-stage declarative language of the Omnicron runtime.

Its full formal name is:

```
Omnicron Axial Lisp
```

Its repository name is:

```
omnicron-axial-lisp
```

Architectural parentage

```
SETCO
classifies the complete ontology.

OMI
defines objects and bounded relations.

Omnicron
provides the portable resolver runtime.

Axial Lisp
provides the canonical programmable declaration language.

Meta-CONS
provides the reflective metaobject protocol.

The Omnicron Coproduct Partition
provides distributed blackboard composition.
```

Meaning of “Axial”

An Axial Lisp value is not identified by one fixed tuple position.

It is resolved at the intersection of typed axes:

```
scope

binding class

structural position

evaluation policy

origin

time

integrity

carrier

projection

orientation
```

The runtime is therefore axial rather than tuple-based.

Canonical language equation

```
Axial Lisp
=
SEXPR homoiconicity
+
MEXPR surface lowering
+
FS/GS/RS/US scope
+
typed environment dispatch
+
origin-tagged coproduct injection
+
ordered CONS resolution
+
multi-stage normalization
+
portable carrier projection
```

Metaobject protocol

```
Meta-CONS
```

is the controlled reflective protocol through which Axial Lisp exposes:

```
scope lookup

binding dispatch

operand evaluation

macro and FEXPR expansion

source injection

CONS resolution

coproduct mediation

chart normalization

projection routing

host capability binding
```

Module family

```

```

One-line definition

> Axial Lisp is a homoiconic declarative Lisp whose programs, data, metadata, scopes, remote contributions, and projection rules share one canonical CONS representation and are resolved dynamically at the intersection of typed runtime axes.

Final boundary

```
Axial Lisp is the language.

Omnicron is the runtime.

OMI is the object model.

SETCO is the ontology.

Meta-CONS is the metaobject protocol.

Coproduct Partition is the distributed composition law.
```
